Demo RStudio and EDA

This is an R Markdown Notebook. When you execute code within the notebook, the results appear beneath the code.

Try executing this chunk by clicking the *Run* button within the chunk or by placing your cursor inside it and pressing *Cmd+Shift+Enter*.

Add a new chunk by clicking the *Insert Chunk* button on the toolbar or by pressing *Cmd+Option+I*.

When you save the notebook, an HTML file containing the code and output will be saved alongside it (click the *Preview* button or press *Cmd+Shift+K* to preview the HTML file).

Exercise 8 from ISLR Chapter 2

The following illustrate commands for exploring this exercise using R and various packages for the `Collage` data.

Libraries

Try to load the `ISLR` library

```
library(ISLR)
```

If it is not available you will need to install the library from CRAN. Click on *Packages* then *Install*. Enter the package name then click on the Install button.

You can also install from the console/command line using `install.packages("ISLR")`.

Ready?

Getting the College data

Next we will need to load the dataset. This is part of the library so we will not need to read it in using `read.csv` but rather we will use the `data` function to load it from the library.

```
data(College)
```

This loads the dataframe `College`. Note you can always see the content of any `R` object by simply typing its name.

For information about the variables, read the text or enter

```
help(College)
```

The info will appear in the `help` tab.

To see explore the data, you can use the command `View(College)`.

This will open a new tab, where you may scroll left and right to look at the rows and columns. In the `View` you should see that the first column is the College/University name. These can be extracted using `rownames(College)`. Let's print out the first 5

```
rownames(College)[1:5]
```

```
## [1] "Abilene Christian University" "Adelphi University"
## [3] "Adrian College"               "Agnes Scott College"
## [5] "Alaska Pacific University"
```

Summary

```
summary(College)
```

```

```

Dimensions of Data

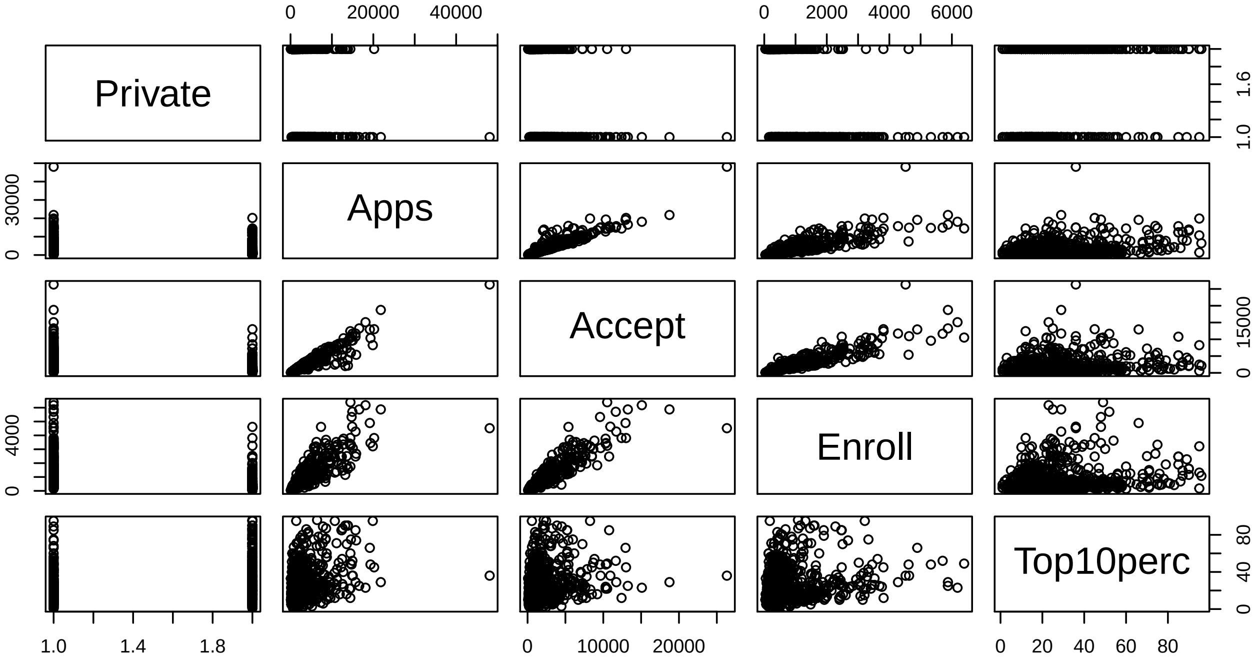
How many observations and variables are in the dataframe?

Suppose we want to refer to those numbers in the text. We can extract them using n = 777 and d = 18. Look at the code to see how we extracted them

Scatter plot matrices

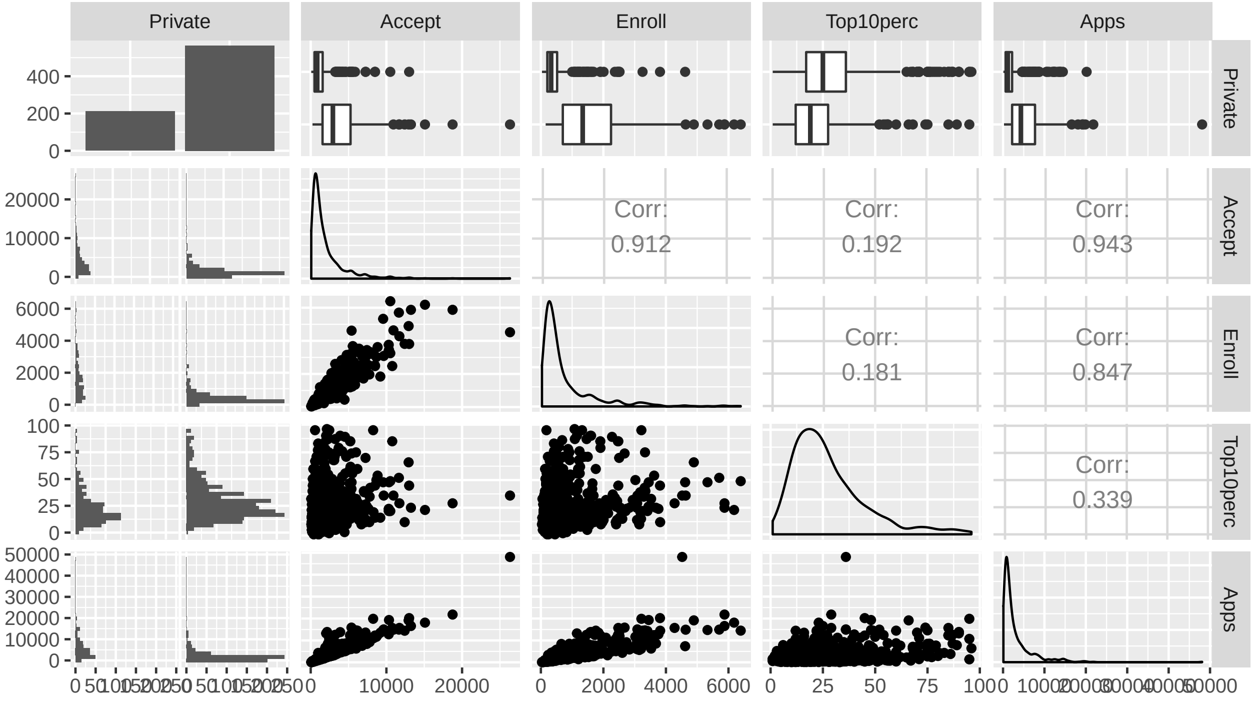
There `base R` version of scatter plot matrices is obtained using the `pairs` function to plot all variables versus each other. We can use subsetting of columns of the dataframe to look at the first 5 columns.

```
pairs(College[, 1:5])
```



We can also look at this using the `ggpairs` function. Install the library `GGally` if it is not available (and any dependent libraries) and load it.

```
library(GGally)
ggpairs(College, columns= c(1,3:5, 2))
```



Energetic Students: how do I suppress the message output so that it does not appear in my document ? Post on Piazza if you know or make a pull request!

The ggpairs function realizes that the variable Private is categorial and plots side by side histograms. The density plots are also useful for seeing the skewness in the marginal distributions.

What other features do these plots indicate? *(Think about assumptions for linear regression)*

New variables

Let's create a new variable Elite by binning the Top10perc variable. We are going to divide universities into two groups based on whether or not the proportion of students coming from the top 10% of their high school classes exceeds 50 %. We will use the library dplyr to illustrate some of the possible transformations and the idea of pipes, which are quite powerful once you get the hang of them!

```
library(dplyr)
```

```
##
## Attaching package: 'dplyr'

## The following object is masked from 'package:GGally':
##
##     nasa

## The following objects are masked from 'package:stats':
##
##     filter, lag

## The following objects are masked from 'package:base':
##
##     intersect, setdiff, setequal, union
```

```
College = College %>%
  mutate(Elite = factor(Top10perc > 50)) %>%
  mutate(Elite =
           recode(Elite, 'TRUE' = "Yes", 'FALSE'="No"))
```

What is the above doing? Document the code here.

Compare to the base R code:

```
Elite=rep("No",nrow(College))
Elite[College$Top10perc >50]="Yes"
Elite=as.factor(Elite)
college=data.frame(College ,Elite)
```

How many Elite universities are there?

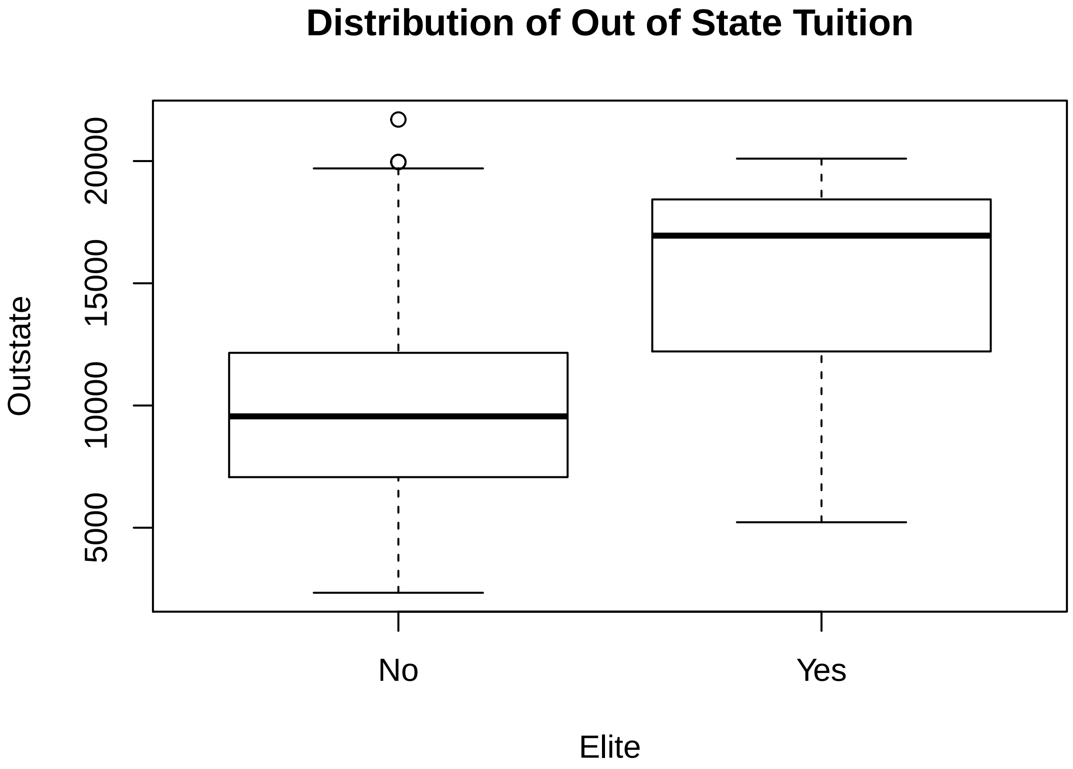
```
summary(College$Elite)
```

```
##  No Yes
## 699  78
```

Side by Side Boxplots

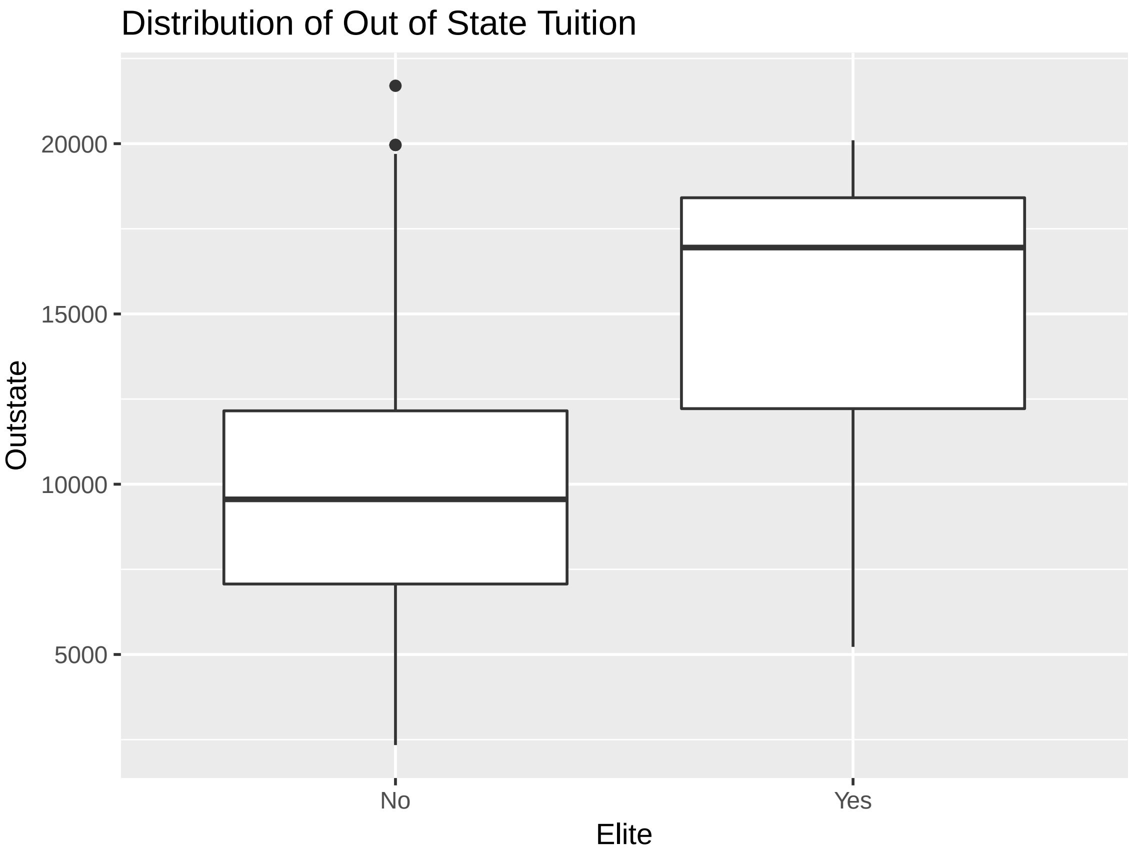
Let's plot the variable Outstate versus Elite using side-by-side boxplots. Using base R we would enter

```
boxplot(Outstate ~ Elite, data=College,
        ylab="Outstate", xlab="Elite")
title("Distribution of Out of State Tuition")
```



Now for the ggplot version:

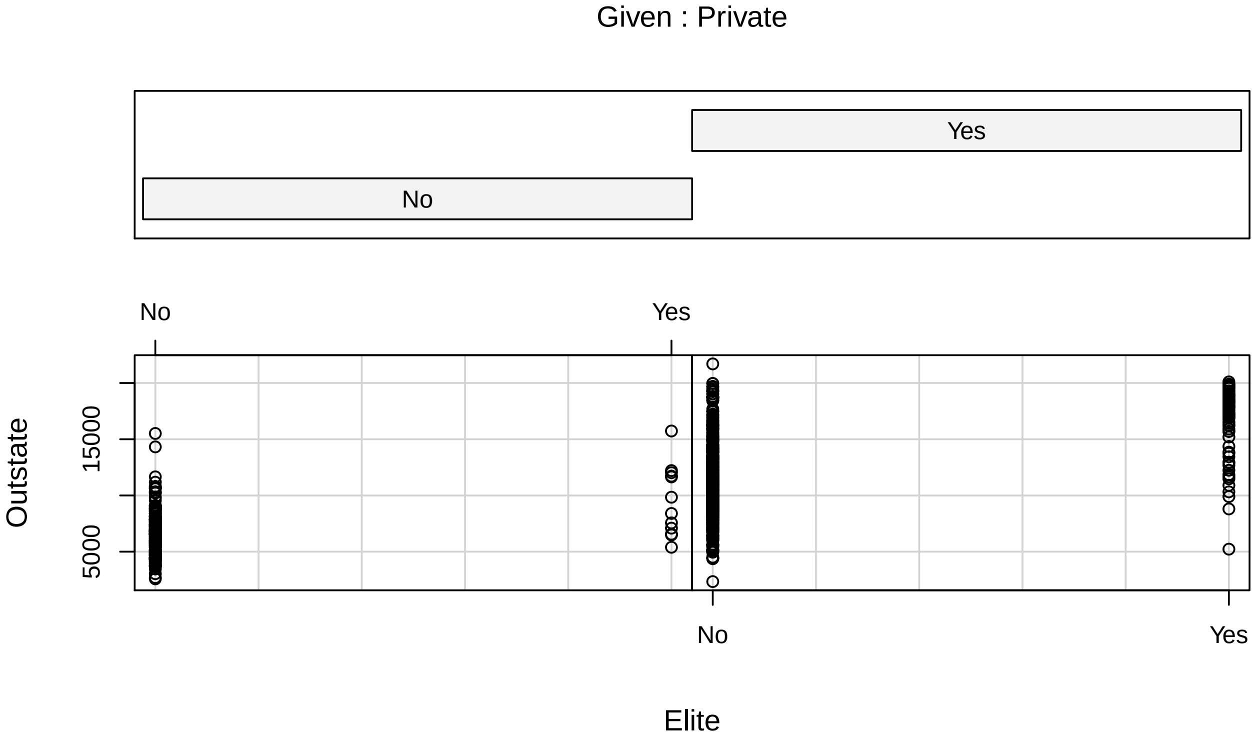
```
library(ggplot2)
my.bp <<-ggplot(data=College, aes(y= Outstate, x=Elite)) # Creates boxplots
my.bp <- my.bp + geom_boxplot() # Adds color
my.bp <- my.bp + ggtitle("Distribution of Out of State Tuition") # Adds a title
my.bp <- my.bp +  ylab("Outstate") + xlab("Elite") # Adds lables for axes
my.bp # displays the boxplots
```



Conditional Plots

Let's look at the distribution of Out of state tuition versus Elite status for Private versun Public universities using *conditional plots*

```
coplot(Outstate ~ Elite | Private, data=College)
```



Energetic Student: Please improve upone the above plot using ggplot and post to Piazza or issue a pull request

Next Steps

Update this document and explore the other variables thinking about the objective of predicting `Apps`. Provide a brief summary of what you discover thinking about models to predict `Apps`.
